ABSTRACT

Carica papaya leaves have been used in folk medicine for centuries. In addition to the nutritional value of its fruit, the leaves of C. papaya possess medicinal properties and are widely used in traditional medicines. This study was conducted to determine the effect of C. papaya leaves extract capsules (CPC) in acute febrile illness with thrombocytopenia. An observational, prospective, uncontrolled, open label, single centre study in Indian patients. Total 80 patients were enrolled in the study. These subjects were randomized into two groups of 40, including the control and intervention groups (received two CPC three times daily). The result showed that CPC had significant increased the platelet count (p<0.05) and maintained stability of hematocrit in the normal level. Carica papaya leaf extract could be used as an additional or as a complementary drug in acute febrile illness patients with thrombocytopenia; it accelerates the increase in the platelet count and shorten the hospitalization thereby reducing the cost of hospitalization significantly.

Key-words: Carica, fever, thrombocytopenia

INTRODUCTION

Carica papaya (C. papaya) is a member of the caricaeae and is a dicotyledonous, polygamous and diploid species.[1] It originated from Southern Mexico, Central America and the northern part of South America. It is now cultivated in many tropical countries such as India, Bangladesh, Indonesia, Sri Lanka, Philippines, West Indies and Malaysia. The papaya fruit is globally consumed either in its fresh from or the form of juices jams and crystallized dry fruit. The ripe fruit is said to be a source of vitamin A, C and calcium. There are many commercial products derived from the different parts of the C. papaya plant, the most prominent being papain and chymopapain which is produced from the latex of the young fruit, stem, and the leaves.

C. papaya leaves have been used in folk medicine for centuries. Recent studies have shown its beneficial effect as an anti-inflammatory agent, for its wound healing properties [2] anti-tumor as well as immunomodulatory effects[3] and as an antioxidant.[4] A toxicity study (acute, subacute, and chronic toxicity) conducted on Sprague Dawley rats administered with C. papaya leaves juice revealed that it was safe for oral consumption.[5] Safety studies based on OECD (Organization of economic Cooperation and development) guidelines for acute, subacute and chronic toxicity conducted on C. papaya extract and showed that it was found to be safe for human consumption.[5]

The leaves of papaya have been showed to contain many active components. That can increase total antioxidant activity in blood and reduce lipid peroxidation level, such as paper chymopapain, cystatin, tocopherol, ascorbic acid, flavonoids, cyanogenic-glycosides glucosinolates.[3]

The alkaloids, flavonoids, saponins, tannin, and glycosides are related with anti-inflammatory activity. C. papaya leaves extract also found to have anti-bacterial effect [6], anti tumor, and immunomodulation activities. The leaf of C. papaya is categorized as non toxic because it’s LD50 >15 g per kg body weight. The leaves also contain cardiac glycosides, anthraquinones, carpaine, pseudocarpaine, phenolic compounds.[7,8]
In addition to the nutritional value of its fruit, the leaves of C. papaya possess medicinal properties and are widely used in traditional medicines. Previous studies in papaya have shown that seed extract of C. papaya possess pharmacological activities, including antihelminthic, antifertility, contraceptive etc. A hot-water extract of the leaves is taken orally as an antipyretic, treatment of anemia and appetite stimulation. In other countries the leaves extract of C. papaya had been effectively used for treatment of dengue fever disease associated with thrombocytopenia.[9]

This study was conducted to determine the effect of C. papaya leaves extract capsules (CPC) in acute febrile illness with thrombocytopenia.

MATERIALS AND METHODS

Study Design
An observational, prospective, uncontrolled, open label, single centre study in Indian patients.

Place and Duration of Study
Patients were enrolled from indoor patient medicine department of a tertiary care hospital from January 2014 to November 2015.

Methodology
Total 80 patients were enrolled in the study. These subjects were randomized into two groups of 40, including the control and intervention groups (received two CPC three times daily). Before screening all participating patients received full verbal and written details of the study including study procedure and use in the subject information sheet. Before enrolling, informed patient consent was obtained by their signing of the informed consent form. At screening, enrolment was based on eligibility criteria, medical history and clinical examination. Demographic information such as age, sex, height and weight were recorded. Pre-study physical examination was carried out at physician’s discretion. All information obtained during screening was entered in the case report form.
The inclusion criteria were as follows: Adult males or females, age more than 18 years; patients with fever of less than one month duration, platelet count less than 100000/µl and voluntary patient consent. All pregnant and lactating females were excluded from the study. Patients < 18 years; and with history of allergic drug reactions were excluded from the study.

RESULTS

The result showed that CPC had significant increased the platelet count (p<0.05) and maintained stability of hematocrit in the normal level.

![Figure 1: Graph showing the change in platelet count of all subjects](image-url)
The rise of platelet counts in the intervention group is ‘J’ shaped and shallow ‘u’ in the control group respectively, demonstrating faster and significant rise of platelets during the critical phase of defervescence. (Figure 1) Statistical analysis with dependent t test showed significant differences of platelet count. (p<0.05)

Figure 2: Graph showing the change in hematocrit levels (%) of all subjects

Hematocrit levels remained stable in intervention group but change in hematocrit levels in intervention and control group were statistically insignificant.

DISCUSSION

Thrombocytopenia often characterized by platelet count less than 150000 per µl of blood is more prevalent and could be due to a decreased platelet production and/or increased destruction. Thrombocytopenia is associated with symptoms as bruising, purpura in forearms, pinpoint hemorrhages, nose bleeds, and bleeding gums.

Clinical manifestations of Thrombocytopenia are mild as long as platelet counts are above 20,000/µl and are generally limited to easy bruising. Once the count goes below 10000/µl the risk of spontaneous mucocutaneous bleeding (gingival bleed, epistaxis, menorrhagia, petechiae and ecchymoses) and life threatening spontaneous intracranial hemorrhage or gastrointestinal bleeding increases rapidly.[10]

Treatment is guided by etiology and disease severity. The main concept in treating thrombocytopenia is to eliminate the underlying problem, whether that means discontinuing suspected drugs that cause thrombocytopenia, or treating underlying sepsis.

Corticosteroids, intravenous immunoglobulin, and splenectomy remain mainstays of treatment however, newer therapies including rituximab and the thrombopoietin receptor agonists are remodeling conventional treatment algorithms. In severe cases and associated with bleeding platelet transfusion is recommended.

All these above mentioned treatment options have their own advantages and disadvantages.

Therefore in the current lieu, consideration for alternate therapies to combat the low platelet count, which is relatively free from the toxic side effects of the drug, should be given.

Certain genes have been shown to influence platelet production and platelet aggregation, namely the Arachidonate 12-lipoxygenase (ALOX 12) also known as the Platelet-type Lipoxygenase as well as the Platelet-Activating Factor Receptor (PTAFR). An increase in activity of these genes is required for platelet production and activation. The ALOX 12 gene is strongly expressed in megakaryocytes and has been known to be responsible for the 12-Hydroxyeicosatetraenoic acid (12-HETE) production of platelets.[11] The PTAFR gene has been found to be expressed in megakaryocytes indicating that it could be a precursor for platelet production in addition to its well known role in platelet aggregation.
ALOX 12 is known to be associated with increased megakaryocyte production as well as its conversion to platelets through 12-HETE mediated pathway which in turn leads to increased platelet production. The active ingredients of C. papaya up regulate the ALOX 12 and PTAFR gene thereby leading to an increased production of megakaryocytes and its conversion into platelets. Clinical evidence shows that, C. papaya extract increases ALOX 12 activity 15 fold and PTAFR activity 13.42 fold which is responsible for increased platelet production.[12]

Fenny Yunita et al. showed that C. papaya leaves juice significantly accelerates the rate of increase in platelet count among patients with dengue fever and dengue hemorrhagic fever.[13] Nisar Ahmed demonstrated rise of platelet count from 55000/µl to 168000/µl after C. papaya leaves extract in dengue fever patient.[14]

Our study results were also consistent with these previous studies.

CONCLUSION

C. papaya leaf extract could be used as an additional or as a complementary drug in acute febrile illness patients with thrombocytopenia; it accelerates the increase in the platelet count and shorten the hospitalization thereby reducing the cost of hospitalization significantly.
